ICE Example

ICE produces a trajectory through the multi-dimensional space of time, \$ & kW (and/or some other measure of interest).

Every 15 min (or whatever the sample period is), the \$ cost is calculated.

The units of the \$ axis are: incremental \$ such that the total bill is the sum of all points. This allows user to do process-run costing and use the built in OLAP rollup functions

Predicted values can be optionally added in

Sensitivity analysis can be seen by viewing down the t axis - you see the Cost/Load shape for a given time
